Study objective + data description

Objective: use dimensionality reduction techniques to identify relationships between categories of each descriptive variable with the categories of car's evaluation level, and visualize them for pattern recognition.

Database: contains examples with the structural information removed, i.e., directly relates car acceptability (evaluation level) to the six input attributes

Variable Type: Categorical

Instances: 1728

Missing Values: No

Categories of car evaluation (target variable in the original study):

class: unacceptable, acceptable, good, very good

Categories of input attributes (feature variables in the original study):

buying price: vhigh, high, med, low

price of the maintenance: vhigh, high, med, low

number of doors: 2, 3, 4, 5more

capacity in terms of persons to carry: 2, 4, more

the size of luggage boot: small, med, big

estimated safety of the car: low, med, high

Table 1: Car evaluation and Buying price

Contingency Table:

	high	low	med	vhigh
acc	108	89	115	72
good	0	46	23	0
unacc	324	258	268	360
vgood	0	39	26	0

CA output Table

C. Eval	Inertia	Ctr 1	Ctr 2
acc	6.812	0.272	74.967
good	48.804	47.815	7.198
unacc	13.275	11.666	17.832
vgood	40.625	40.247	0.004

Price	Inertia	ctr1	ctr2
high	21.139	19.295	18.693
low	50.245	48.792	13.582
Med	8.948	6.161	30.155
vhigh	29.184	25.752	37.57

P-value for Pearson Chi-square test ~ 0

- We reject H0: dependency exists
- Variance explained by first 2 eigenvectors: 99.6%
- Price: Inertia is very high for "Low"
- Car Evaluation: Inertia is very high for "good" and "vgood"
- Conclusion: Negative Relationship

buying price and evaluation (factor map)

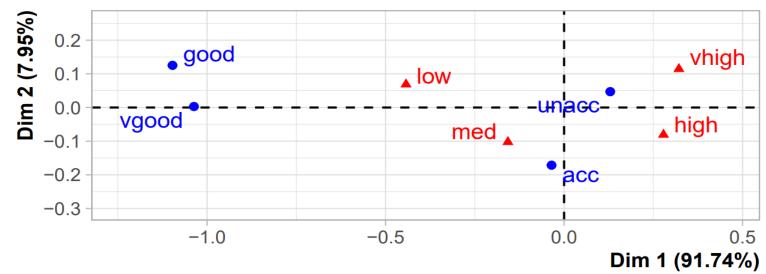

Table 2: Car evaluation and price of maintenance

Contingency Table:

- P-value for Pearson Chi-square test ~ 0
- We reject H0: dependency exists
- Variance explained by first 2 eigenvectors: 100%
- safety: Inertia is high for "low" safety
- Car Evaluation: Inertia is high for "acc"
- Conclusion: Positive Relationship

safety level and evaluation (factor map)

Comparison: original study and our analysis

Our findings are consistent with the original analysis in several key areas, such as the strong influence of buying and maintenance prices on car acceptability.

High buying prices and maintenance cost are strongly associated with lower car acceptability while
 Lower buying prices and maintenance cost show a relationship with higher acceptability

The original analysis also highlighted the significant impact of safety levels and luggage boot size and person carrying capacity on the car's evaluation, which aligns with our results.

- Lower safety levels are strongly associated with lower acceptability and higher safety levels
 relate with better acceptability.
- Lower person capacity (2 persons) has a relationship with lower acceptability while higher person capacity is related to higher acceptability.
- Smaller luggage boot size is associated with lower acceptability while Medium and large boot sizes are related to higher acceptability.

Multidimensional Scaling

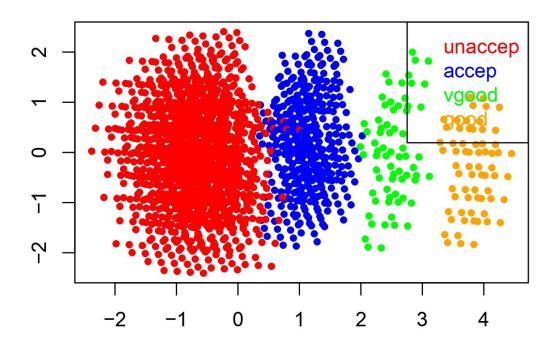

Method:

- Original data is represented in 7 dimensions
- Used ordinal encoding to preserve order
- Scaled the data
- Calculated Euclidean distance for each instance
- Higher distance ~ more *dissimilarity*

Observations:

- Dimensionality reduction to 2 dimensions
- Instances of a particular class are closer

MDS: Car Evaluation

Conclusion

- Using correspondence analysis after developing different contingency tables we have illustrated key relationships between a car's acceptability with six other car attributes
- Many of the relationships that were found in the original study (machine learning models) align with our results
- Multidimensionality Scaling helps visualize the data in reduced dimensions while simultaneously
 preserving the dissimilarity based on car acceptability
- The insights from this study can be used to generate an understanding of how car acceptability classifiers (based on machine learning models) are actually functioning
